# Chapter outline

---

## 7.1. Clustering in Mobility Data

## 7.2. Moving Clusters for Capturing Collective Mobility Behavior

## 7.3. Sequence Pattern Mining in Mobility Data

## 7.4. Prediction and Classification in Mobility Data

## 7.5. Summary

## 7.1. Clustering in mobility data

# Trajectory clustering

- Technical objectives:
  - Cluster trajectories w.r.t. similarity
    - For each cluster, find its 'centroid' or 'representative'
  - Discover moving clusters (flocks), outliers, etc.
- Issues:
  - Which distance between trajectories? recall Chap. 6
  - Which kind of clustering? Partitioning (K-means-like) vs. Density-based (DBSCAN- or OPTICS- like) solutions
  - How does a cluster 'centroid' or 'representative' look like?

# Trajectory clustering (cont.)

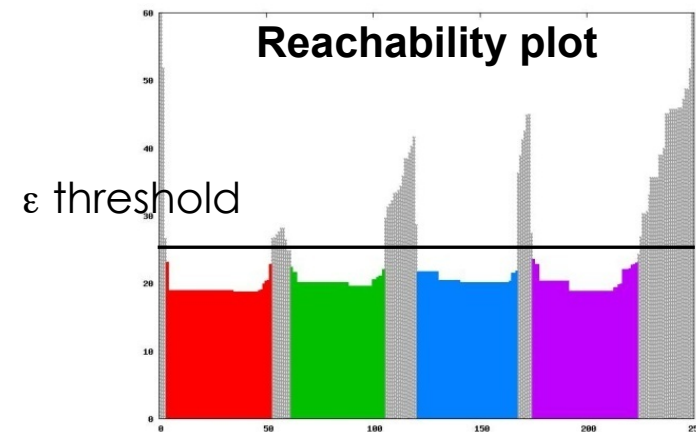

- General requirements:
  - Tolerance to noise; Low computational cost; Applicability to complex, possibly non-vectorial data; Non-spherical clusters; etc.
  - E.g.: A traffic jam along a road = “snake-shaped” cluster

- State-of-the-art
  - Clustering on entire trajectories: **T-OPTICS** (2006), **CenTR-I-FCM** (2009)
  - Clustering on sub-trajectories: **TRACCLUS** (2007), **NEAT** (2012)

# T-OPTICS (Trajectory OPTICS)

- Builds upon OPTICS and the DISSIM function between trajectories
- Reachability plot (valleys and hills)
  - Valleys  $\rightarrow$  clusters
  - Hills  $\rightarrow$  noise

# CenTR-I-FCM (Clustering under uncertainty)

- Builds upon Fuzzy-C-Means (a variation of K-means for uncertain data)

- Motivation:

- uncertainty of trajectory data should be taken into account

- Three phases:

- Step 1: **mapping** of trajectories in an intuitionistic fuzzy vector space
- Step 2: **discovering the centroid** of a bundle of trajectories (algorithm CenTra)
- Step 3: **clustering** trajectories under uncertainty (algorithm CenTR-I-FCM)

# TRACCLUS (Trajectory Clustering)

- Discovers similar portions of trajectories (sub-trajectories)

- Works in two phases:

- **partitioning**
- **grouping**

# TRACCLUS (cont.)

## Algorithm TRACCLUS

Input: A dataset of trajectories  $D=\{tr_1, \dots, tr_N\}$

Output: (1) A set of clusters  $C=\{C_1, \dots, C_O\}$ , (2) A set of representative trajectories

/\* Partitioning phase \*/

1. for each  $tr_i$  in  $D$  do
2.     Execute trajectory partitioning; Get a set  $S$  of line segments as the result;
3.     Accumulate  $S$  into a set  $D'$ ;

/\* Grouping phase \*/

4. Execute Line Segment clustering for  $D'$ ;

Get a set  $C$  of clusters as the result;

5. for each  $C_j$  in  $C$  do

6.     Execute RTG;
- Get a representative trajectory as the result;

- Clusters trajectories moving on road network.
- Works in three phases:
  - **base cluster formation**: partitions trajectories into t-fragments, where each one lies on a single road segment, and forms base clusters, each containing the t-fragments that lie on the same road segment
  - **flow cluster formation**: combines base clusters w.r.t. merging selectivity
    - function that takes into account flow, density and road speed factors
  - **flow cluster refinement**: compresses flow clusters (DBSCAN variant)

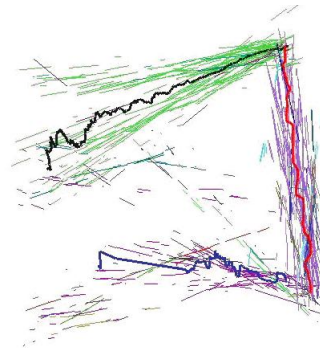

# NEAT example

# Finding representatives

- ... in trajectory datasets
- Recall one of the trajectory clustering issues:
  - How does a cluster 'centroid' or 'representative' look like?
- Some of the trajectory clustering algorithms inherently provide such 'centroids' or 'representatives' (actually, artificial trajectory-like shapes)
  - TRACCLUS representatives
  - CenTR-I-FCM centroids

# Finding representatives (cont.)

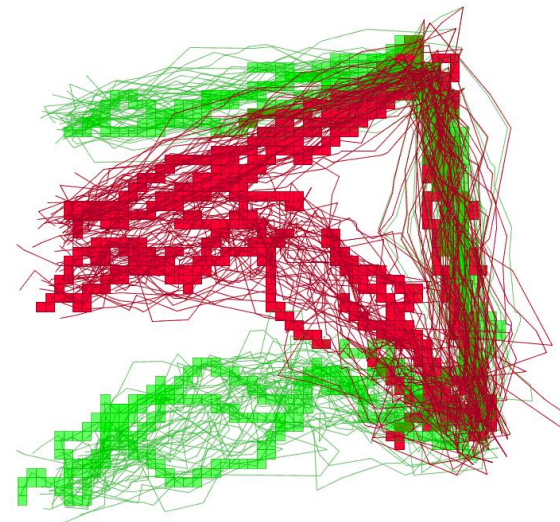

## ■ TRACCLUS representatives

- three thick lines (black, red, blue)
- compositions of segments (sub-trajectories)
- a trajectory may be split into different clusters

## ■ CenTR-I-FCM centroids

- two sets of cells (green, red)
- catch the overall complex mobility patterns

# Finding representatives (cont.)

- Another approach: **T-sampling** (2010, 2012)
  - Samples the top-k most representative trajectories ...
  - ... following a deterministic voting methodology
- Trajectory segmentation is neighborhood- rather than geometry-aware!

- Example:

(a)

(b)

(c)

(d)

## 7.2.

Moving clusters for  
capturing collective  
mobility behavior

# Flocks and variants

- **Flock**: a large enough subset of objects moving along paths close to each other for a certain time

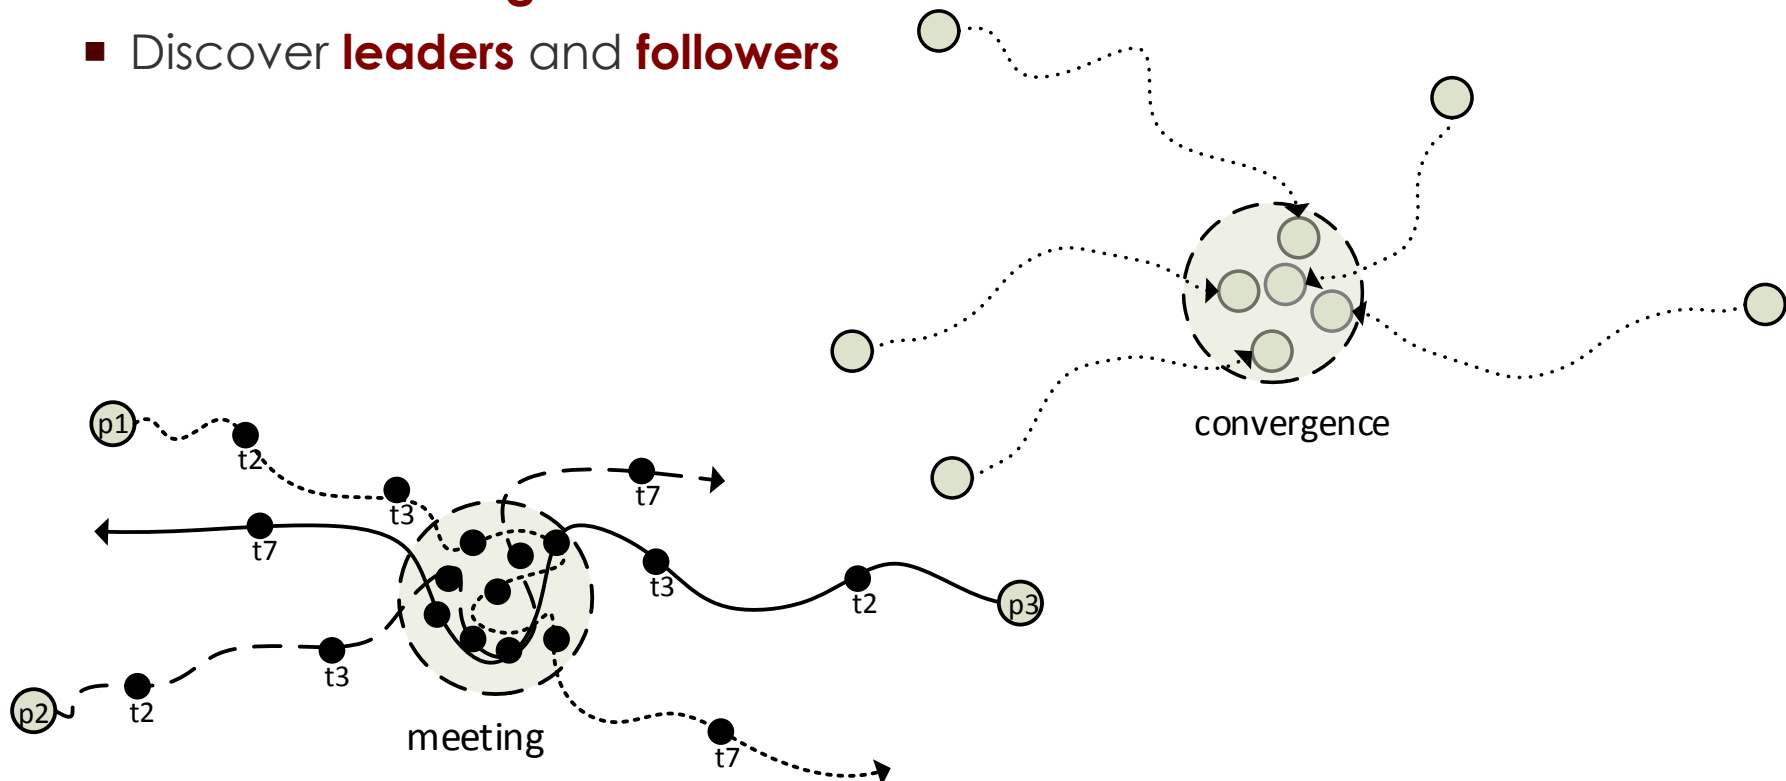

- Side-effect:  
the **lossy-flock problem**

# Flocks and variants (cont.)

- Interesting problems arise over the flock concept:
  - Identify long flock patterns (**top-k longest flock pattern discovery**)
  - Discover **meetings** (fixed- vs. varying- versions)
  - Discover **convergences**
  - Discover **leaders** and **followers**

# Moving clusters

- **Moving cluster:** a sequence of spatial clusters in consecutive timepoints that keep a large percentage of common objects
  - a kind of varying flock

- Example:

- Issue:
  - The 'consecutive time' constraint may result in the loss of interesting patterns

# Convoys

- **Convoy**: a group of objects that has at least  $m$  objects, which are density-connected with respect to a distance threshold  $e$ , during  $k$  consecutive timepoints

# Group patterns and Swarms

- **Group pattern:** a set of moving objects that travel within a radius for certain timestamps that maybe non-consecutive
  - actually, a time-relaxed flock pattern
- **Swarm:** a collection of moving objects with cardinality at least  $m$ , that are part of the same cluster for at least  $k$  timepoints
  - timestamps are not required to be consecutive
  -

## 7.3. Sequence pattern mining in mobility data

# Frequent pattern mining

- Technical objectives:
  - Identify 'frequent' or 'popular' patterns
  - Discover hot spots, hot paths, etc.
- Two groups of approaches:
  - techniques that identify regularities in the behavior of a single user: **Periodic patterns** (2007)
  - techniques that reveal collective sequential behavior of a set of users: **T-Patterns** (2007)

- **T-pattern** is a sequence of visited regions, frequently visited in a specific order with similar transition times
- Example:
  - TP1:  $\langle(), A\rangle \langle(9,15), B\rangle$  (supp:31)
  - TP2:  $\langle(), A\rangle \langle(4,20), C\rangle$  (supp:26)
  - TP3:  $\langle(), A\rangle \langle(9,12), B\rangle \langle(10,56), D\rangle$  (supp:21)

## Algorithm T-Pattern (with static regions of interest - Rol)

Input: (1) a set of input trajectories  $T$ , (2) a grid  $G_0$ , (3) a minimum support/density threshold  $\delta$ , (4) a radius of spatial neighborhoods  $\varepsilon$ , (5) a temporal threshold  $\tau$ .

Output: A set of pairs  $(S, A)$  of sequences of regions with temporal annotations.

1.  $G = \text{ComputeDensity}(T, G_0, \varepsilon)$ ;
2.  $\text{Rol} = \text{PopularRegions}(G, \delta)$ ;
3.  $D = \text{Translate}(T, \text{Rol})$ ;
4.  $\text{TAS\_mining}(D, \delta, \tau)$ ;

## 7.4. Prediction and classification in mobility data

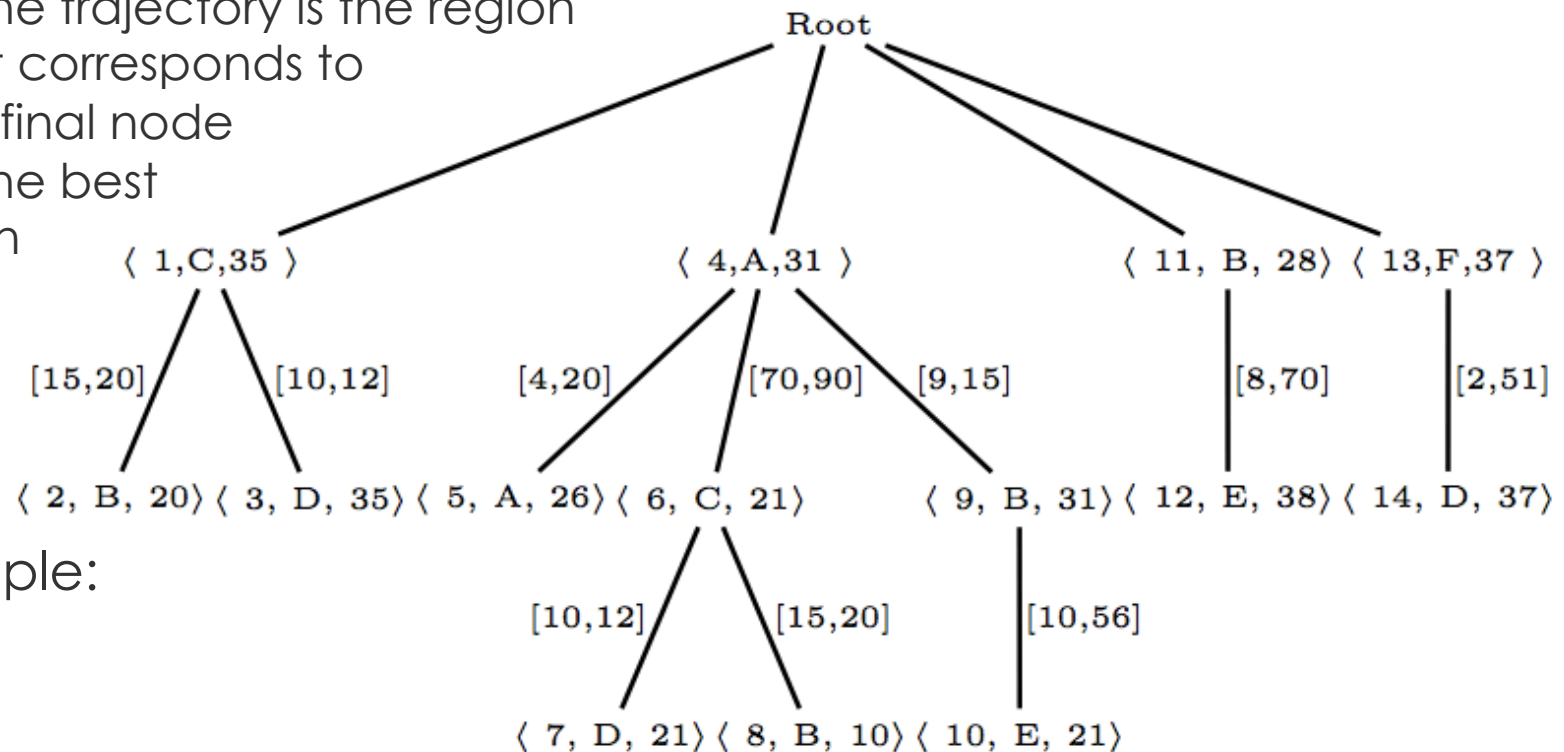

# Prediction and Classification

- Goal: to predict the future location of a moving object
- Possible solutions:
  - Naïve : extrapolate w.r.t. current location and velocity vector
  - Alternative: build a prediction model
- State-of-the-art technique:
  - **WhereNext** (2009)

# WhereNext

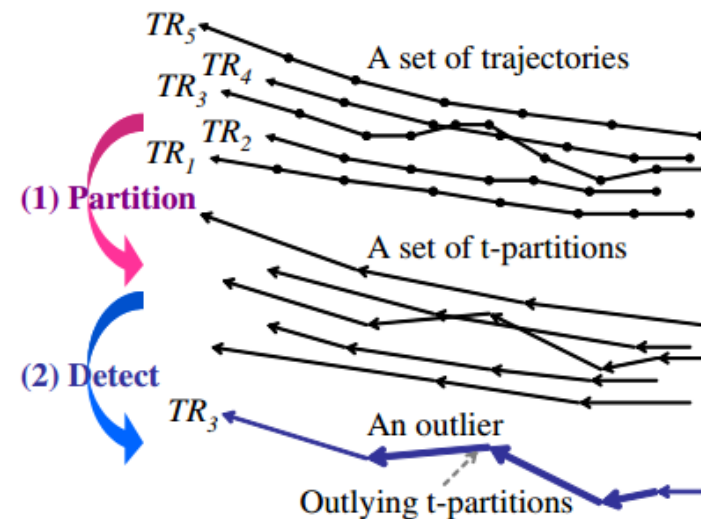

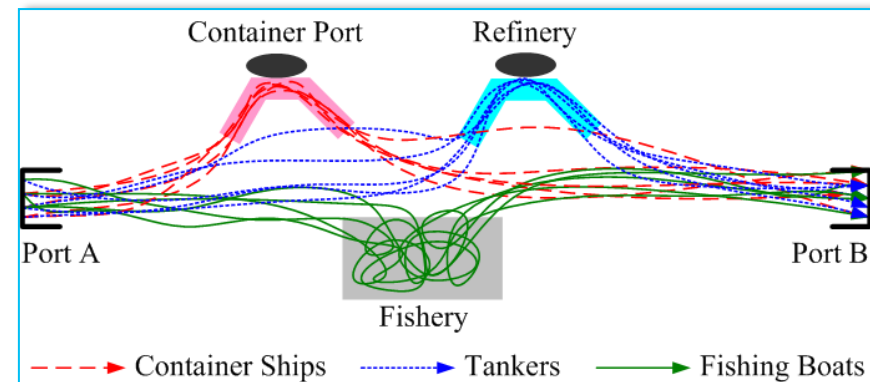

- Builds upon the T-pattern concept: extracts a set of T-patterns and builds a T-pattern tree
- the best path is found for a given trajectory
- the predicted future location of the trajectory is the region that corresponds to the final node of the best path

- Example:

# Classification and Outlier detection

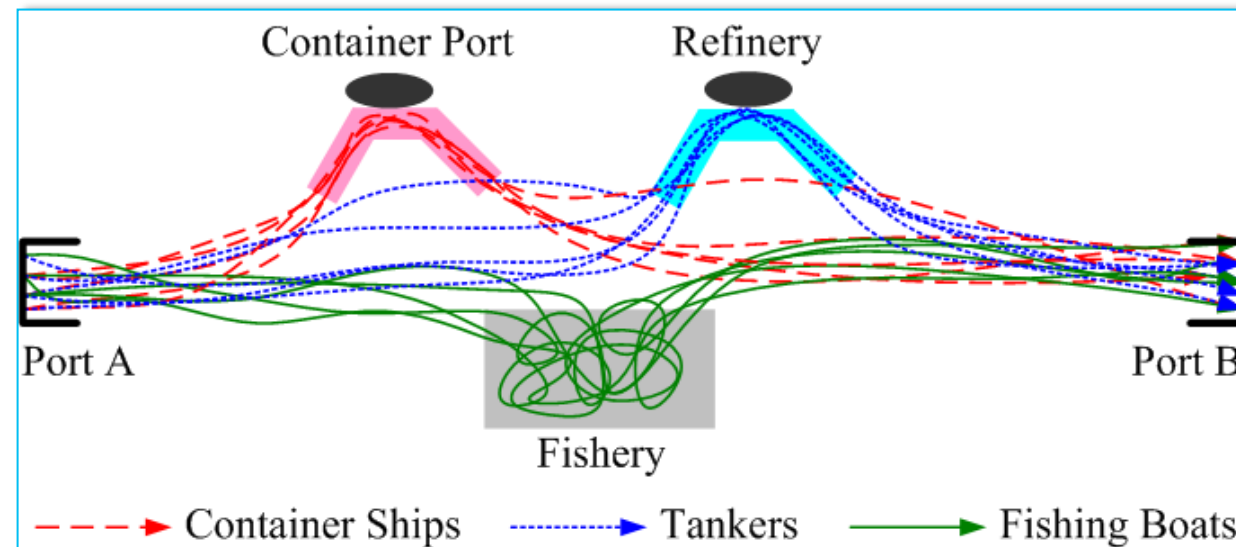

- **Classification** aims to predict the class label of a moving object based on its trajectories (and eventually other features)
  - State-of-the-art:  
**TRACCLASS** (2008)
- **Outlier detection** aims to detect among a set of trajectories, those that behave differently from their neighbors
  - State-of-the-art:  
**TRAOD** (2008)

# TRACCLASS

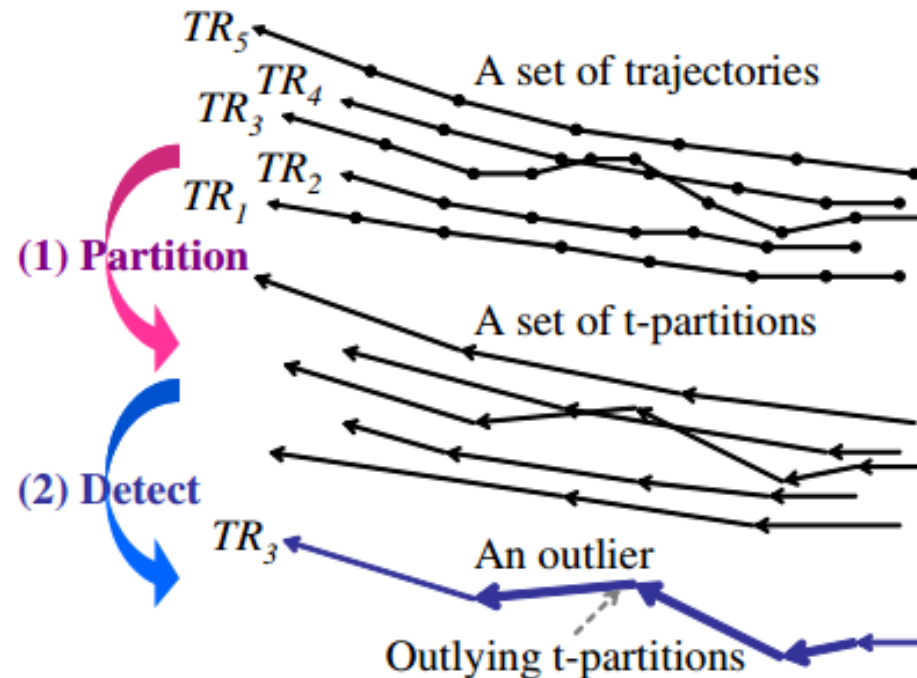

- **TRACCLASS** (Trajectory Classification) works in three phases:
  1. Partitions trajectories based on their shapes (using a TRACCLUS variant)
  2. Discovers regions that contain sub-trajectories mostly from one class (hierarchical region-based clustering)
    - Tradeoff between homogeneity and conciseness
  3. Discovers common movement patterns for each class of sub-trajectories (trajectory-based clustering)

- Example:

- **TRAOD** (Trajectory Outlier Detection) works in two phases:
  - Partitioning phase: trajectories are segmented into t-partitions (sub-trajectories); recall TRACCLUS
  - Detection phase: a trajectory is considered outlier if it contains a sufficient number of outlying t-partitions

- Example:

30

## 7.5. Summary

# Summarizing ...

- Knowledge discovery in trajectory databases discovers behavioral patterns of moving objects
- In this chapter, we presented state-of-the-art techniques for:
  - Clustering a set of trajectories
  - Discovering collective behaviors (flocks, moving clusters, etc.)
  - Predicting the future location of moving objects
  - Classification and outlier detection

End of chapter
